

1 Trend analysis for USFWS species status assessment for
2 bull trout (*Salvelinus confluentus*)

7 This draft manuscript is distributed solely for purposes of scientific peer review. Its content is
8 deliberative and predecisional, so it must not be disclosed or released by reviewers. Because
9 the manuscript has not yet been approved for publication by the U.S. Geological Survey
10 (USGS), it does not represent any official USGS finding or policy.

Background

The purpose of this analysis is to estimate trends in the abundance (counts) of bull trout within predefined core areas spread across Oregon, Washington, Idaho, and Montana.

Data

I provided a template for the data in a “tidy” format, which consisted of the following 8 fields:

- `dataset` (i.e., integer value for unique ID)
- `recovery unit` (e.g., Mid Columbia)
- `core area` (e.g., South Fork Clearwater)
- `popn/stream` (e.g., Crooked River)
- `metric` (e.g., abundance, survival)
- `method` (e.g., redd survey, electrofishing)
- `year`
- `value` (i.e., generally a count)

Data files were provided to me by data coordinators from each of the four states. They are:

- Oregon: Stephanie Gunckel (ODFW)
- Washington: Marie Winkowski (WDFW)
- Idaho: Brett Bowersox (IDFG)
- Montana: Dan Brewer (USFWS), Clint Muhlfeld (USGS), Tim Cline (USGS)

The data coordinators also provided me with some metadata indicating which of the data specific to a location were generally for adults versus juveniles.

Modeling framework

Population model

I fit discrete-time versions of exponential models for population growth (decline), such that the abundance of bull trout (N) is a function of the initial population size N_0 , time (t), the population growth rate (u), and a time-dependent stochastic effect of the environment (w). Specifically, in continuous time the model is

$$N(t) = N_0 \exp(u) \exp(wt). \quad (1)$$

In discrete time, with a time step of 1 unit (e.g., a year), the model becomes

$$N_t = N_{t-1} \exp(u + w_t). \quad (2)$$

39 If we take the logarithm of both sides and define $x_t = \log(N_t)$, we have

$$x_t = x_{t-1} + u + w_t. \quad (3)$$

40 Further defining $w_t \sim N(0, q)$ leads us to a so-called “biased random walk” model, where u is
 41 the tendency for the population to increase or decrease each time step (i.e., the bias), and
 42 w_t is some unknown stochastic aspect of the environment that partially drives population
 43 dynamics.

44 **Observation model**

45 The data available to us rarely come from complete censuses, and instead are typically derived
 46 from partial counts. Furthermore, mistakes may occur when counting individuals or redds.
 47 Thus, we should account for these possible sampling or observation errors with a so-called
 48 “data model”.

49 In this case, we assume that the data in hand are a somewhat distorted view of the “true
 50 state of nature”, such that the logarithm of the observed count at time t (y_t) equals that of
 51 the true count plus or minus some error. Specifically, we can write this as

$$y_t = x_t + a + v_t \quad (4)$$

52 where a is an offset to account for partial sampling, and $v_t \sim N(0, r)$.

53 **State-space model**

54 We can combine equations (3) and (4), along with a definition for the initial state (x_0), into
 55 a so-called “state-space model”, where

$$\begin{aligned} y_t &= x_t + a + v_t \\ x_t &= x_{t-1} + u + w_t \\ x_0 &\sim N(\mu, \sigma) \end{aligned} \quad (5)$$

56 **Multiple populations**

57 Here we want to estimate the annual change in population size for each of the many different
 58 core areas across the four states. Furthermore, some core areas comprise several different
 59 populations/locations, so we need to frame our state-space model in a multivariate context.

60 Observation model

61 If we have n different populations within a core area, then our observation model becomes

$$y_{i,t} = x_{i,t} + a_i + v_{i,t} \quad (6)$$

62 where $y_{i,t}$ is the log-count for population i and year t , a_i is an offset to account for partial
63 sampling in population i , and $v_{i,t} \sim N(0, r_i)$ ¹. We can combine each of the population specific
64 observation models into a matrix form, such that

$$\begin{aligned} y_{1,t} &= x_{1,t} + a_1 + v_{1,t} \\ y_{2,t} &= x_{2,t} + a_2 + v_{2,t} \\ &\vdots \\ y_{n,t} &= x_{n,t} + a_3 + v_{n,t} \end{aligned} \quad (7)$$

65 becomes

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}_t = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}_t + \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix} + \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix}_t, \quad (8)$$

66 or more compactly in matrix notation as

$$\mathbf{y}_t = \mathbf{x}_t + \mathbf{a} + \mathbf{v}_t. \quad (9)$$

67 where \mathbf{y}_t , \mathbf{x}_t , \mathbf{a} , \mathbf{v}_t are all $n \times 1$ vectors, and $\mathbf{w}_t \sim \text{MVN}(\mathbf{0}, \mathbf{Q})$.

68 Population model

69 Just as we did for the observation model, we can write the models for population dynamics as

$$x_{i,t} = x_{i,t-1} + u_i + w_{i,t} \quad (10)$$

70 where u_i is the bias, which is unique to each population², and $w_{i,t} \sim N(0, q_i)$ ³.

¹Here the variance of the observation errors is assumed to be population specific, but it might be reasonable to assume that each survey/census type might have the same variance, such that $v_{i,t} \sim N(0, r)$.

²It might be reasonable to assume that some/all of the populations have the same bias, given their membership within a core area.

³Here the variance of the process errors is assumed to be population specific, but it might be reasonable

71 We can again express all of the population models in matrix form, such that

$$\begin{aligned}
x_{1,t} &= x_{1,t-1} + a_1 + w_{1,t} \\
x_{2,t} &= x_{2,t-1} + a_2 + w_{2,t} \\
&\vdots \\
x_{n,t} &= x_{n,t-1} + a_3 + w_{n,t}
\end{aligned} \tag{11}$$

72 becomes

$$\begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}_t = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}_t + \begin{bmatrix} u_1 \\ u_2 \\ \vdots \\ u_n \end{bmatrix} + \begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_n \end{bmatrix}_t, \tag{12}$$

73 or more compactly in matrix notation as

$$\mathbf{x}_t = \mathbf{x}_{t-1} + \mathbf{u} + \mathbf{w}_t \tag{13}$$

74 where \mathbf{x}_t , \mathbf{x}_{t-1} , \mathbf{u} , \mathbf{w}_t are all $n \times 1$ vectors, and $\mathbf{w}_t \sim \text{MVN}(\mathbf{0}, \mathbf{Q})$.

75 State-space forms

76 At this point, however, we are assuming that the monitoring data for each population is telling
77 us something about only the specific population itself, rather than contributing information
78 to the population trend at the larger scale of their core area, which is the really the scale
79 of interest here. Thus, we need to modify our equations to accommodate this hierarchical
80 framework.

81 For example, assume that we have $p = 2$ core areas (call them A and B), each with data
82 from 2 representative populations. In this case, $n = 4$, but the number of states (i.e., the
83 number of rows in \mathbf{x}_t) is 2, so we need a way to “map” each of the observed time series onto
84 its respective core area. We begin by writing out the equations for the observations in long
85 matrix form akin to equation (8), such that

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix}_t = \begin{bmatrix} x_A \\ x_A \\ x_B \\ x_B \end{bmatrix}_t + \begin{bmatrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{bmatrix} + \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}_t, \tag{14}$$

to assume that they all have the same variance, given their membership within a core area, such that $w_{i,t} \sim \text{N}(0, q)$.

Because both x_A and x_B appear twice in equation (14), we can use a 4×2 matrix of 1's and 0's as our map. Specifically, we have

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix}_t = \begin{bmatrix} 1 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_A \\ x_B \end{bmatrix}_t + \begin{bmatrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{bmatrix} + \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}_t, \quad (15)$$

We can write equation (15) more compactly in matrix notation as

$$\mathbf{y}_t = \mathbf{Z}\mathbf{x}_t + \mathbf{a} + \mathbf{v}_t. \quad (16)$$

where \mathbf{y}_t , \mathbf{a} , and \mathbf{v}_t are all $n \times 1$ vectors, \mathbf{Z} is an $n \times k$ matrix, and \mathbf{x}_t is a $k \times 1$ vector.

The equation for the population dynamics in each of the 2 core areas then becomes

$$\begin{bmatrix} x_A \\ x_B \end{bmatrix}_t = \begin{bmatrix} x_A \\ x_B \end{bmatrix}_{t-1} + \begin{bmatrix} u_A \\ u_B \end{bmatrix} + \begin{bmatrix} w_A \\ w_B \end{bmatrix}_t, \quad (17)$$

which can be written more compactly in matrix notation as

$$\mathbf{x}_t = \mathbf{x}_{t-1} + \mathbf{u} + \mathbf{w}_t, \quad (18)$$

and combined with equation (16) to form the full multivariate state-space model

$$\begin{aligned} \mathbf{y}_t &= \mathbf{Z}\mathbf{x}_t + \mathbf{a} + \mathbf{v}_t \\ \mathbf{x}_t &= \mathbf{x}_{t-1} + \mathbf{u} + \mathbf{w}_t. \end{aligned} \quad (19)$$

Thus, by simply altering the dimensions of \mathbf{Z} , and the locations of 1's and 0's within it, we can evaluate any number of different hypotheses about how the population dynamics are structured spatially. For example, if we set \mathbf{Z} equal to an $n \times n$ identity matrix, where

$$\mathbf{Z} = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix}, \quad (20)$$

then each of the time series of data is assumed to represent a unique state of nature. If, on the other hand, we set \mathbf{Z} equal to an $n \times 1$ column vector of 1's, such that

$$\mathbf{Z} = \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}, \quad (21)$$

then each of the time series of data is assumed to represent a sample from a single state of nature.

Variance specification

The multivariate state-space model allows us to be quite specific about how the observation errors (\mathbf{v}_t) and process errors (\mathbf{w}_t) are related to one another, if at all. In the most simple case, the errors could be independent and identically distributed (IID), such that (for the observation variance)

$$\mathbf{R} = \begin{bmatrix} r & 0 & \cdots & 0 \\ 0 & r & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & r \end{bmatrix}. \quad (22)$$

Alternatively, the errors might be independent, but not identically distributed

$$\mathbf{R} = \begin{bmatrix} r_1 & 0 & \cdots & 0 \\ 0 & r_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & r_n \end{bmatrix}, \quad (23)$$

or identically distributed, but not independent

$$\mathbf{R} = \begin{bmatrix} r & c & \cdots & c \\ c & r & \cdots & c \\ \vdots & \vdots & \ddots & \vdots \\ c & c & \cdots & r \end{bmatrix}. \quad (24)$$

Model fitting

All models were fit using the `{MARSS}` package (Holmes *et al.* 2012, 2020) for the **R** computing software (R Core Team 2020). All of the data and code necessary to reproduce the results of the analysis can be found online at <https://github.com/mdscheuerell/bulltrout>.
